

Projection variability of attitude complements across different operators

We present experimental data that the projection of the content of attitude complements (i) varies between entailment-canceling operators, and (ii) that this by-operator variation differs between attitude predicates. The observed variability is not captured by existing theoretical accounts of projection (e.g., Heim 1983; van der Sandt 1992; Abrusán 2011; Schlenker 2021), but suggests that an analysis must consider interactions between predicates and operators, which cannot be fully determined by lexical classes. Instead, our results reveal a more nuanced picture of lexical semantic and pragmatic properties, which raises important questions for future research on projection.

Projection across entailment-cancelling operators. Language users may infer that a speaker who utters an attitude ascription, as in (1), is committed to the content of the complement (CC), even when it occurs under an entailment-canceling operator, like negation (1a), polar questions (1b), modals (1c), or conditionals (1d), in which case we say that it *projects*.

- (1) a. **Negation:** *‘Cole didn’t discover that Julian dances salsa.’*
b. **Polar Question:** *‘Did Cole discover that Julian dances salsa?’*
c. **Modal:** *‘Perhaps Cole discovered that Julian dances salsa.’*
d. **Conditional:** *‘If Cole discovered that Julian dances salsa, Logan will be joyful.’*

Current research only rarely examines projectivity differences across these operators, with conflicting findings. Karttunen (1971) proposed a distinction between English factive predicates (e.g., *be annoyed, regret*), where the CC projects across all four operators, and semi-factives (e.g., *discover, realize, see, notice*) where it only projects across negation. Comparing different types of contents, Smith and Hall (2014) found that the projective content of epithets and the CC of *know* was more projective under negation than conditionals, whereas the content of non-restrictive relative clauses and the preparatory content of *win* showed the opposite pattern. Further, Sieker and Solstad’s (2022) investigation of the projection of the CC of German purported factive and semi-factive predicates replicated Smith and Hall’s (2014) result for the German counterpart of ‘know’ (*wissen*), but as part of a pattern of overall higher projectivity under negation than other operators. They found no interaction with predicate type, or evidence for the (semi-)factive distinction.

All of these studies suggest a comparatively high projectivity across negation, but the results diverge about whether they found interactions between operators and different types of contents. To investigate if the different results are due to variation between English and German, differences in contents being tested, or methodological differences, we conducted a series of experiments designed to investigate projection from under the four entailment-canceling operators in (1), using the same projection measure as Sieker and Solstad (2022) (the ‘certain that’ diagnostic; see e.g., Tonhauser et al., 2018; Djärv and Bacovcin, 2017; Mahler, 2020) and applied it to the CC of 20 English clause-embedding predicates, including factive predicates (*be annoyed, know, reveal*) and semi-factives (*discover, see*), as well as 15 non-factive predicates, due to recent findings that their complements are also projective, albeit to varying degrees (Degen and Tonhauser 2022). Our study aimed to replicate the projection variability across operators of various English projective contents reported in Smith and Hall (2014) for English attitude complements.

Method. Projection of the CC of the 20 attitude predicates was measured in four sets of experiments: The predicates were embedded in polar questions in Exps. 1, under negation (Exps. 2), under *perhaps* (Exps. 3), and in conditional antecedents (Exps. 4). (Each set contained three experiments using different at-issueness measure in a separate block. Here, we focus on the projection ratings.) In each experiment, participants read utterances like those in (1) and judged whether the speaker (who was named) was certain of the CC (e.g.: Is [the speaker] certain that Julian dances salsa?). Participants gave their response on a slider marked ‘no’ (coded as 0) at one end and ‘yes’ (coded as 1) on the other. Each participant saw all 20 attitude predicates (each paired with a unique content from a set of 20 contents) under one operator. We analyze data from 2,682 self-reported

native speakers of American English recruited on Prolific or Amazon’s MT platform.

Results and Analysis. Figure 1 shows mean projection ratings for the 20 attitude predicates by operator; predicates are ordered by their mean rating across all operators (*be annoyed* has the highest overall mean). We find (i) by-operator differences in projectivity, and (ii) differences in by-operator variability between predicates. The generalization (i) is supported by significant main effects of operator in the linear mixed effects models shown in Table 1. (ii) is supported by the fact that there are at least 34 significant interaction terms in these models (out of 57 possible interactions of operator and predicate). Specifically, the models in Table 1 illustrate specific differences across the predicates in by-operator variation with different reference levels for predicate: For instance, whereas the CC of *be annoyed* projects more from under negation (and questions) than conditionals and modals, the CC of *discover* projects less from negation than conditionals and questions, and more from under negation than modals, and the CC of *know* projects less from under negation than questions, but more from under negation than modals, while the difference between negation and conditionals is not significant here. Therefore, we did not replicate the result from Smith and Hall (2014), that the CC of *know* projects more from negation than conditionals. Given that our findings indicate many interaction effects of operator and predicate throughout, our results also differ from Sieker and Solstad’s (2022) findings for German, where no such interactions were found. Further, the variability we found is gradient, confirming previous research that by-predicate variability is not determined by categorical lexical classes (Tonhauser et al. 2018; Degen and Tonhauser 2022), and extending this result to by-predicate variability in interaction with entailment-cancelling contexts.

Discussion: Implications for projection analyses. Our results—that projection is modulated by entailment-cancelling operators and that there is by-predicate variation in the effect of operator on projection—are not captured by contemporary projection analyses, for several reasons. The first reason is that contemporary analyses do not lead us to expect interactions with different types of entailment-cancelling operators. In Heim 1983, for instance, the CC of (semi-)factive predicates projects to the global context, except when that would produce an inconsistency, in which case the CC is accommodated to the local context of the operator. While it is conceivable for the meaning of the operator to systematically interact with the possibility of local accommodation, no such interaction has been spelled out. The second reason is that many contemporary analyses do not make predictions for the projection of the CC of many of the 20 predicates, as they are limited to (semi-)factive predicates (e.g., Heim 1983; van der Sandt 1992, whose CCs are analyzed as presuppositions) and/or entailed CCs that project unless at-issue with respect to the Question Under Discussion (e.g., Abrusán 2011; Simons et al. 2017). A possible exception is the analysis of Schlenker 2021, which predicts the potential for projection for CCs that are contextually entailed. In the full talk, we discuss how this analysis might be able to capture the gradient projection observed in our experiment. The third reason is that contemporary projection analyses do not make sufficiently fine-grained distinctions between different clause-embedding predicates (but only between whether the CC is a presupposition or entailed). Consequently, they do not make predictions about the by-predicate variation in the effect of operator on projection.

Discussion: Empirical implications and lexical properties. The predicate / operator interactions we find for the selected English attitude predicates are not in line with Sieker and Solstad (2022), who find no such effects for the selected German attitudes, but used the same task as the study presented here. This difference in findings indicates potential cross-linguistic differences in projection variability, which provides an avenue for future research.

Our findings contradict Karttunen’s (1971) distinction between factive and semi-factive predicates: The CC of (factive) *be annoyed* does not project invariably from all four operators, and the CC *discover*, which is considered semi-factive, does not project more from under negation than the

other three operators. The pattern we observed for *know* does not fit into either category. Similar considerations apply to *see* and *reveal*, which are also categorized as (semi-)factive in the literature, thus questioning the defined difference between factive and semi-factive predicates (see also Beaver, 2010). Future research appealing to these categories must clarify their definition. Additionally, claims about projection variability must be relativized to the entailment-canceling operator. Although our data replicate the result from Tonhauser et al. (2018) that, in polar questions, the CC of *discover* is less projective than that of *know*, the same does not hold in conditionals. Finally, our results provide further support (from negation, modals, and conditionals) for the result of Degen and Tonhauser (2022), that projection does not categorically differentiate between (semi-)factive and non-factive predicates: The CCs of *inform* and *acknowledge*, for instance, are at least as projective as that of some (semi-)factive predicates.

So, can the observed interaction between predicate and operator in mean projection ratings be predicted from lexical semantic/pragmatic properties of the predicates, and, if so, how? This is a pressing question for future research, to which our data offer some tentative answers. We identify four major patterns. The predicates *pretend* and *think* exhibit the ‘**Negation high**’ pattern, shown in panel (a) of **Figure 2**: We tentatively hypothesize that negation (but not the other operators) interacts with the semantic or pragmatic antiveridicality associated with these predicates. The inferential predicates *prove*, *confirm*, and *establish* exhibit a ‘**Negation low**’ pattern, shown in panel (b): Here, we tentatively hypothesize that the veridical meaning component interacts with negation (but not the other operators), to result in lower projection ratings under negation. For *announce*, *confess*, *admit*, and *reveal*, the CC is most projective when embedded in conditional antecedents: This ‘**Conditional high**’ pattern (c) may suggest that the discourse effect of a conditional interacts with the change-of-state communication predicates. Finally, the predicates *inform*, *know*, and *be annoyed* exhibit a ‘**Modal low**’ pattern (d). The lexical meaning of these predicates, whose CCs are among the most projective, appears to interact with the modal adverb *perhaps*, yielding lower projection ratings.
