

Projection differs across embedding operators

We present experimental evidence (i) that the projection of the content of attitude complements differs between entailment-canceling operators, and (ii) that this by-operator variation differs between attitude predicates. Our results do not align with the long-standing distinction of factive vs. semi-factive predicates (see, e.g., ???). Instead, the observed by-operator variation reveals a more nuanced picture of lexical semantic/pragmatic properties which raises important questions for future research on projection.

Projection across entailment-cancelling operators. Interpreters may infer that a speaker who utters an attitude ascription, as in (1), is committed to the content of the complement (CC), even when it occurs under an entailment-canceling operator, like negation (1a), polar questions (1b), modals (1c), or conditionals (1d).

- | | | | |
|-----|----|------------------------|--|
| (1) | a. | Negation: | ‘Cole didn’t discover that Julian dances salsa.’ |
| | b. | Polar Question: | ‘Did Cole discover that Julian dances salsa?’ |
| | c. | Modal: | ‘Perhaps Cole discovered that Julian dances salsa.’ |
| | d. | Conditional: | ‘If Cole discovered that Julian dances salsa, Logan will be joyful.’ |

? proposed that the CC of factive predicates (e.g. regret, forget) projects across all four operators, whereas that of semi-factive predicates (e.g. discover, realize, see, notice) always projects from under negation, but not always from under polar questions, modals, or conditionals. To date, systematic empirical investigations of Karttunen’s intuition are scarce.

? investigated by-operator variation (negation, conditional) for various types of projective content, observing that the content of non-restrictive relative clauses and *win* was more projective under conditionals than negation, while *know* and epithets exhibited the opposite pattern. Their task asked participants how surprised they would be to learn the content under investigation after observing the utterance. Since other factors besides speaker commitment modulate (un)expectedness (see e.g. ??), it is unclear that they (only) measured projection. So far, there has been no experimental investigation of by-operator variation comparing factive and semi-factive predicates. However, ? and ? observed by-predicate variation in polar questions. ?, assessing acceptability of affirming the main clause while denying the CC, found higher ratings for *be happy* and *appreciate* (assumed to be factive) and *be aware* than *realize* (assumed to be semi-factive). Here, it is also not obvious how exactly this task relates to projection. ? measured projection of the CC of a broad range of attitude predicates more directly, collecting ratings about speaker certainty about the CC. The observed differences did not match the expectations from Karttunen’s classification (e.g., the CC of semi-factive *realize* was as projective as that of factive *be annoyed* and more than that of semi-factive *discover*).

Experiment. We present results of a study investigating by-operator projection variation for the CCs of 20 attitude predicates, including purported factive and semi-factive predicates (e.g., *be annoyed*, *discover*). Projection was measured across all four operators in (1) using the ‘certain that’ diagnostic for projection (see e.g., ???).

Methods and Expectations. Projection of the CC of the 20 attitude predicate was measured in four sets of experiments: The predicates were embedded under polar questions in Exps.1, under negation (Exps.2), under perhaps (Exps.3), and in conditional antecedents (Exps.4). (Each set of experiments contained three experiments differing in an at-issueness measure used in a separate block. We focus on the projection ratings here.) In each experiment, participants read utterances like those in (1) and judged whether the speaker (who was named) was certain of the CC (e.g.: Is [the speaker] certain that Julian dances salsa?). Participants gave their response on a slider marked ‘no’ (coded as 0) at one end and ‘yes’ (coded as 1) on the other. Each participant saw all 20 attitude predicates (each paired

with a unique content from a set of 20 contents) under one operator. We analyze the data from 2,682 self-reported native speakers of American English recruited on Prolific or Amazon’s MT platform. Karttunen’s generalization leads us to expect the CC of factive predicates to consistently receive relatively high projection ratings under all four operators, and the CC of semi-factive predicates to exhibit high projection ratings under negation and possibly lower ratings under the other operators.

Results. **Figure1** shows mean projection ratings for the 20 attitude predicates by embedding operator; predicates are ordered by their mean rating across all operators (be annoyed has the highest overall mean). We observe by-operator variation in projection means as well as differences across the predicates in by-operator variation: For instance, whereas the CC of be annoyed projects more from under negation (and questions) than conditionals and modals, the CC of know projects less from under negation than questions, but more from under negation than modals, and the CC of discover projects less from negation than conditionals and questions, and more from under negation than modals. These results (supported by linear mixed effects models, see **Table1**) are unexpected based on ?’s (?) distinction between factive and semi-factive predicates: The CC of the purportedly factive predicate be annoyed does not project invariably from all four operators, and the CC of the purportedly semi-factive predicate discover does not project more from under negation than the other three operators. The pattern observed for know is neither that of a factive nor a semi-factive predicate. Similar considerations apply to see and reveal, which are also considered (semi-)factive in the literature.

Discussion: Empirical and theoretical implications. Our results—that projection is modulated by entailment-canceling operators and that there is by-predicate variation in the effect of operator on projection—have several empirical and theoretical implications. First, the results for the predicates typically considered (semi-)factive, (viz. be annoyed, know, see, discover and reveal), call into question the assumed distinction between factive and semi-factive predicates (see also ?). Future research appealing to these categories must clarify their definition. Second, claims about projection variability must be relativized to the entailment-canceling operator. While our data replicate the result from ? that, in polar questions, the CC of discover is less projective than that of know, this result does not carry over to conditionals. Finally, our results provide further support (from negation, modals, and conditionals) for the result of ?, that projection does not categorically distinguish between (semi-)factive and non-factive predicates: The CCs of inform and acknowledge, for instance, are at least as projective as that of some (semi-)factive predicates.

Discussion: Novel research question. Can the observed interaction between predicate and operator in mean projection ratings be predicted from lexical semantic/pragmatic properties of the predicates, and, if so, how? This is a pressing question for future research, to which our data offer some tentative answers. We identify four major patterns. The predicates pretend and think exhibit the ‘**Negation high**’ pattern, shown in panel (a) of **Figure2**: We tentatively hypothesize that negation (but not the other operators) interacts with the semantic or pragmatic antiveridicality associated with these predicates. The inferential predicates prove, confirm, and establish exhibit a ‘**Negation low**’ pattern, shown in panel (b): Here, we tentatively hypothesize that the veridical meaning component interacts with negation (but not the other operators), to result in lower projection ratings under negation. For announce, confess, admit, and reveal, the CC is most projective when embedded in conditional antecedents: This ‘**Conditional high**’ pattern (c) may suggest that the discourse effect of a conditional interacts with the change-of-state communication predicates. Finally, the predicates inform, know, and be annoyed exhibit a ‘**Modal low**’ pattern (d). The lexical meaning of these predicates, whose CCs are among the most projective, appears to interact with the modal adverb perhaps, yielding lower projection ratings.
